What is otosclerosis?
Otosclerosis is the abnormal growth of bone of the MIDDLE ear. This bone prevents structures within the ear from working properly and causes hearing loss. For some people with otosclerosis, the hearing loss may become severe.

How do we hear?
Hearing is a series of events in which the ear converts sound waves into electrical signals and causes nerve impulses to be sent to the brain where they are interpreted as sound. The ear has three main parts: the outer, middle, and inner ear. Sound waves enter through the outer ear and reach the middle ear, where they cause the eardrum to vibrate. The vibrations are transmitted through three tiny bones in the middle ear called the ossicles. These three bones are named the malleus, incus, and stapes (and are also known as the hammer, anvil, and stirrup). The eardrum and ossicles carry the vibrations to the inner ear. The stirrup transmits the vibrations through the oval window and into the fluid that fills the inner ear.

The vibrations move through fluid in the snail-shaped hearing part of the inner ear (cochlea) that contains the hair cells. The fluid in the cochlea moves the top of the hair cells, which initiates the changes that lead to the production of the nerve impulses. These nerve impulses are carried to the brain, where they are interpreted as sound. Different sounds stimulate different parts of the inner ear, allowing the brain to distinguish among various sounds, for example, different vowel and consonant sounds.

How does otosclerosis cause hearing impairment?
Otosclerosis can cause different types of hearing loss, depending on which structure within the ear is affected. Otosclerosis usually affects the last bone in the chain, the stapes, which rests in the entrance to the inner ear (the oval window). The abnormal bone fixates the stapes in the oval window and interferes with sound passing waves to the inner ear.

Otosclerosis usually causes a conductive hearing loss, a hearing loss caused by a problem in the outer or middle ear. Less frequently, otosclerosis may cause a sensorineural hearing loss (damaged sensory cells and/or nerve fibers of the inner ear), as well as a conductive hearing loss.

What causes otosclerosis?
The cause of otosclerosis is not fully understood, although research has shown that otosclerosis tends to run in families and may be hereditary, or passed down
from parent to child. People who have a family history of otosclerosis are more likely to develop the disorder. On average, a person who has one parent with otosclerosis has a 25 percent chance of developing the disorder. If both parents have otosclerosis, the risk goes up to 50 percent. Research shows that white, middle-aged women are most at risk.

Some research suggests a relationship between otosclerosis and the hormonal changes associated with pregnancy. While the exact cause remains unknown, there is some evidence associating viral infections (such as measles) and otosclerosis.

What are the symptoms of otosclerosis?
Hearing loss is the most frequent symptom of otosclerosis. The loss may appear very gradually. Many people with otosclerosis first notice that they cannot hear low-pitched sounds or they can no longer hear a whisper.

In addition to hearing loss, some people with otosclerosis may experience dizziness, balance problems, or tinnitus. Tinnitus is a sensation of ringing, roaring, buzzing, or hissing in the ears or head that accompanies many forms of hearing loss.

How is otosclerosis diagnosed?
An examination by an otolaryngologist or otologist is needed to rule out other diseases or health problems that may cause these same symptoms. An audiologist is a hearing health care professional who is trained to identify, measure, and rehabilitate hearing impairment and related disorders. An audiologist uses a variety of tests and procedures to assess hearing and balance function. The audiologist may produce an audiogram (a graph that shows a person's hearing sensitivity) and a tympanogram (a graph that shows how well the middle ear functions to conduct sound). Discuss these results with your audiologist/otologist.

How is otosclerosis treated?
In many cases surgery is an option for treatment of otosclerosis. In an operation called a stapedectomy, a surgeon (otolaryngologist or otologist) bypasses the diseased bone with a prosthetic device that allows sound waves to be passed to the inner ear.

It is important to discuss the risks and possible complications of this procedure, as well as the benefits, with the surgeon. In rare cases, surgery can worsen the hearing loss.

If the hearing loss is mild, surgery may not be an option. Also, on occasion, some hearing loss persists after surgery. A properly fitted hearing aid may help some people with otosclerosis in situations that include persistent hearing loss.

A hearing aid is designed to compensate for a hearing loss by amplifying sound. An audiologist can discuss the various types of hearing aids available and make
a recommendation based on the specific needs of an individual.

**What research is being done on otosclerosis?**

Scientists are conducting research to improve understanding of otosclerosis. Genetic studies continue in order to identify the gene or genes that may lead to this disorder. Other researchers are studying the effectiveness of lasers currently used in surgery, of amplification devices, and of various stapes prostheses. Improved diagnostic techniques are also being examined and developed.

This document is not intended as a substitute for professional health care.
Did this free publication from VEDA help you?

Thanks to VEDA, vestibular disorders are becoming recognized for their impacts on lives and our economy. We see new diagnostic tools and research studies, more accessible treatments, and a growing respect for how life-changing vestibular disorders can be.

**VEDA provides tools** to help people have a better quality of life: educational materials, support networks, professional resources, and elevated public awareness.

**Your support of VEDA matters.** Please help us to continue providing such great help by becoming a member or donor.

**Members receive** an information packet; discounts on purchases; a subscription to VEDA’s newsletter, *On the Level*, containing information on diagnosis, treatment, research, and coping strategies; and the option of communicating directly with others who understand the personal impacts of a vestibular disorder. Professional members also receive the option to list training opportunities on our site, bulk-discounted prices on patient education materials, and a listing on VEDA’s provider directory, the only of its kind serving patients seeking help from a vestibular specialist.

**SUPPORT VEDA**

**Membership, 1-year**
- $ 40 ... Basic
- $110 ... Professional

Memberships include electronic & online newsletter & free publications. For hard copies, include optional shipping fees.

- $ 5 ... Shipping (domestic)
- $ 15 ... Shipping (international)

$________ Please indicate your desired subscription amount here.

**Optional Contribution**
I’d to support VEDA with a donation (instead of or in addition to membership).

$________ Please indicate your desired subscription amount here.

☐ Check this box if you prefer that your donation remain anonymous.

$________ Total

**PAYMENT INFORMATION**
If you prefer, you can make your purchases online at [http://www.vestibular.org](http://www.vestibular.org).

☐ Check or money order in US funds, payable to VEDA (enclosed)

☐ Visa ☐ MC ☐ Amex
