Persistent Postural-Perceptual Dizziness

Based on an article written by Dr. Jeffrey P. Staab, with edits by Brandy Hollins, AuD incorporating updates from the Bárány Society and ICD-11 in 2017.

HISTORY

In 1986, German neurologists Thomas Brandt and Marianne Dieterich first described a condition that they called phobic postural vertigo (PPV). Symptoms included postural dizziness without vertigo and fluctuating unsteadiness provoked by environmental or social stimuli (e.g., crowds), which could not be explained by some other neuro-otologic disorder. Triggers included a pre-existing vestibular disorder, medical illness or psychological stress.

Behavioral criteria of PPV included the presence of an obsessive-compulsive personality, mild depression, and anxiety. Studies on PPV showed that it was NOT a psychiatric disorder, but rather a neuro-otologic condition with behavioral elements.

In the early 2000s, the American team of Jeffrey Staab, Michael Ruckenstein, & their colleagues performed studies to update the concept of PPV and described the clinical syndrome of chronic subjective dizziness (CSD). The symptoms of CSD included non-vertiginous dizziness and unsteadiness that was increased by a person’s own motion, exposure to environments with a complex or moving stimuli (e.g., stores, crowds), and performance of tasks that required precise visual focus (e.g., reading, using a computer).

Other vestibular experts described space-motion discomfort and visual vertigo, symptoms that overlapped to some extent with PPV and CSD.

In 2010, scientists from around the world began a process of identifying the most important features of these syndromes. In early 2014, they reached a consensus on the key symptoms and defined a diagnosis of Persistent Postural-Perceptual Dizziness (PPPD).

The World Health Organization has included PPPD in its draft list of diagnoses to be added the next edition of the International Classification of Diseases (ICD-11) in 2017.

In 2017, the World Health Organization officially recognized PPPD, classifying it under the code AB32.0 in the 11th edition of the International...
THE PRIMARY SYMPTOMS OF PPPD ARE PERSISTENT SENSATIONS OF ROCKING OR SWAYING UNSTEADINESS AND/OR DIZZINESS WITHOUT VERTIGO LASTING 3 MONTHS OR MORE.

Classification of Diseases (ICD-11) within the section of Diseases of the Inner Ear. This classification aligns with the diagnostic criteria for PPPD as outlined in a 2017 consensus document by Staab and researchers for the Committee for the Classification of Vestibular Disorders of the Bárány Society.

**Symptoms**

- The primary symptoms of PPPD are persistent sensations of rocking or swaying unsteadiness and/or dizziness without vertigo lasting 3 months or more.
- Symptoms are typically experienced on most days, often intensifying as the day progresses, though severity can fluctuate. They occur more frequently than not, being present for at least 15 days in a 30-day period, with many patients experiencing daily occurrences.
- Symptoms are present on more days than not (at least 15 of every 30 days); most patients have daily symptoms.
- Symptoms are typically worse with:
  - Upright posture (standing or sitting upright)
  - Movement of the head or body, whether self-generated or caused by external forces (e.g. being in a moving vehicle)
  - Exposure to visually complex or motion-rich environments (e.g. busy patterns on floors or walls, graphics or images displayed on large screens)
- PPPD typically starts shortly after an event that causes acute vertigo, unsteadiness, dizziness, or disruption of balance such as:
  - A peripheral or central vestibular disorder (e.g., BPPV, vestibular neuritis, Meniere’s disease, stroke)
  - Vestibular migraine
  - Panic attacks with dizziness
  - Mild traumatic brain injury (concussion or whiplash)
  - Dysautonomia (disease of the autonomic nervous system)

Other medical problems, such as dysrhythmias and adverse drug reactions that manifest with acute bouts of vertigo, unsteadiness or dizziness are less common triggers of PPPD.

PPPD rarely starts slowly and gradually without a triggering event, although it is not always possible to sort out the cause. In such scenarios, it is recommended that the patient maintain a log of their symptoms (roughly over a period of 6 to 12 months) and undergo regular examinations to enable a conclusive diagnosis.

Anxiety or mild depression may be present as comorbidities. However, they are not symptoms of PPPD, as they were with PPV. Previous studies suggest that a history of anxiety disorders may be a risk factor for developing PPPD.

PPPD may coexist with other vestibular disorders, which can confuse the diagnosis since patients may exhibit other symptoms, including vertigo.

Patients with PPPD may have a history of vertigo, suggesting a previous vestibular dysfunction. Patients typically exhibit chronic symptoms due to accumulated exposure to motion stimuli, making them more susceptible to recurrence of symptoms.

Patients with PPPD avoid situations that may exacerbate symptoms because they don’t want to feel worse physically. Some patients also avoid these situations because they are afraid that something terrible might happen. Thus PPPD is a **physiological** disorder that can have **psychological** consequences.

**DIAGNOSIS**

Physical exams, laboratory tests, and neuroimaging are NOT used to diagnose PPPD itself, but to identify potentially comorbid conditions, which can lead to a suspected diagnosis of CSD.
Physical examination and laboratory testing are often normal or may show a current or previous vestibular problem that does not fully explain the patient’s symptoms.

The Bárány Society established the following diagnostic criteria for Persistent Postural-Perceptual Dizziness. All five (A-E) criteria must be fulfilled in order to meet the diagnosis. 2

- One or more symptoms of dizziness, unsteadiness, or non-spinning vertigo are present on most days for 3 months or more.
  - Symptoms last for prolonged periods of time (hours) but may wax and wane in severity.
  - Symptoms need not be present continuously throughout the entire day.
- Persistent symptoms occur without specific provocation, but are exacerbated by three factors:
  - Upright posture
  - Active or passive motion without regard to direction or position, and
  - Exposure to moving visual stimuli or complex visual patterns.
- The disorder is precipitated by conditions that cause vertigo, unsteadiness, dizziness, or problems with balance including acute, episodic, or chronic vestibular syndromes, other neurologic or medical illnesses, or psychological distress.
  - When the precipitant is an acute or episodic condition, symptoms settle into the pattern of criterion A as the precipitant resolves, but they may occur intermittently at first, and then consolidate into a persistent course.
  - When the precipitant is a chronic syndrome, symptoms may develop slowly at first and worsen gradually.
- Symptoms cause significant distress or functional impairment.
- Symptoms are not really accounted for by another disease or disorder.

**BEHAVIORAL FACTORS**

Behavioral assessment of PPPD patients may be normal and/or show anxiety and depression. Other psychiatric disorders may also present.

Behavioral factors contribute to PPPD in three ways:

- Individuals with anxious, introverted temperaments or a pre-existing anxiety disorder may be predisposed to PPPD after a precipitating event;
- Individuals who exhibit a high level of anxiety while they are experiencing vestibular symptoms may be more likely to develop PPPD;
- A primary predictor of PPPD is when a patient who first experiences an acute vestibular episode displays high levels of anxiety and caution, coupled with expectations for a negative outcome. This heightened anxiety is like a self-fulfilling prophesy, in that the result is generally a poor rate of recovery.

High anxiety intensifies postural instability and reactivity to motion stimuli during acute vestibular trauma and slows recovery by preventing the patient from developing adaptive strategies.

Anxiety and depression can increase the likelihood of developing PPPD.

- 60% of patients with PPPD had clinically significant anxiety;
- 45% of patients had clinically significant depression;
- 25% of patients had neither.

**TREATMENT**

By 2014, no large scale, randomized, controlled trials of therapeutic interventions for CSD had been conducted, but several smaller studies have been completed around the world.

**Medication**

In clinical trials for the use of SSRIs (selective serotonin reuptake inhibitors) and SNRIs (serotonin norepinephrine reuptake inhibitors) on patients with CSD:

- Primary symptoms were reduced by at least half in 60%-70% of patients to entered the trials and 80% of patients who completed at least 8-12 weeks of treatment;
- Dropout rates due to medication intolerance averaged 20% (adverse effects included nausea, sleep disturbance, and sexual dysfunction).

Patients who do not respond to one SSRI have a good chance of responding to another one.
Increased dizziness was rarely observed, and comorbid anxiety and depression were improved. Treatment must be maintained for at least one year or more to minimize relapse.

Benzodiazepines and other vestibular suppressants are NOT effective as a primary treatment for PPPD. 

**Vestibular Balance Rehabilitation Therapy (VBRT)**

Vestibular/balance rehabilitation therapy works to desensitize or habituate patients to motion stimuli.

In 2014, the first small study on the efficacy of VBRT specifically for PPPD patients was completed. Its results support previous clinical experience and suggest the following:

- VBRT reduces the severity of vestibular symptoms by 60%-80%, resulting in increased mobility and enhanced daily functioning;
- VBRT may be effective in reducing anxiety and depression in PPPD patients;
- Patients should continue VBRT for 3-6 months to receive maximum benefit from the treatments.

**Counseling**

Psychotherapy is not a very successful treatment for fully established, longstanding PPPD, but it may be able to reduce the chances of developing PPPD if used early. Older trials showed that cognitive behavioral therapy (CBT) had a moderate effect for reducing dizziness in patients with PPPD, but, unfortunately, the benefits did not last after therapy was finished. More recent trials showed that just three CBT sessions resulted in significantly reduced dizziness and dizziness-related avoidance symptoms when treatment was started within 8 weeks of the triggering event (i.e., as PPPD symptoms were starting, but before they were fully established). Under those circumstances, the benefits seemed to last.

In 2020, a small study on a multimodal, interdisciplinary therapy program showed improvement in symptoms in patients with PPPD as well as other chronic vestibular disorders. This study emphasizes the effectiveness of combined therapeutic approaches, with treatment including a combination of CBT, VRT, and medication. However, there is a lack of large-scale, randomized controlled trials in this area. 4

**MECHANISMS**

Research studies are beginning to uncover physiologic processes associated with PPPD. Investigations have provided hints about alterations in postural control, visual perception of space, and processing of vestibular and visual stimuli in the brain. More details should be forthcoming over the next few years.
